

The format of this leaflet was determined by the Ministry of Health and its content was checked and approved by the Ministry of Health on September 2017.  
The leaflet was updated according to the instructions of the Ministry of Health on February 2019.

## **1. Name of the medicinal product**

**AMARYL 1mg, 2mg, 3mg, 4mg**  
Glimepiride tablets

## **2. Therapeutic indications**

Amaryl is indicated for non-insulin-dependent diabetes melitus (adult-onset diabetes, type II diabetes), when diet, regular physical exercise and weight reduction alone cannot maintain therapeutically suitable blood glucose levels.

### **Limitations of Use**

AMARYL should not be used for the treatment of type 1 diabetes mellitus or diabetic ketoacidosis, as it would not be effective in these settings.

## **3. DOSAGE AND ADMINISTRATION**

### **3.1 Recommended Dosing**

AMARYL should be administered with breakfast or the first main meal of the day.

The recommended starting dose of AMARYL is 1 mg or 2 mg once daily. Patients at increased risk for hypoglycemia (e.g., the elderly or patients with renal impairment) should be started on 1 mg once daily [see *Warnings and Precautions (5.1)* and *Use in Specific Populations (8.5, 8.6)*].

After reaching a daily dose of 2 mg, further dose increases can be made in increments of 1 mg or 2 mg based upon the patient's glycemic response. Uptitration should not occur more frequently than every 1 to 2 weeks. A conservative titration scheme is recommended for patients at increased risk for hypoglycemia [see *Warnings and Precautions (5.1)* and *Use in Specific Populations (8.5, 8.6)*].

The maximum recommended dose is 8 mg once daily.

Patients being transferred to AMARYL from longer half-life sulfonylureas (e.g., chlorpropamide) may have overlapping drug effect for 1 to 2 weeks and should be appropriately monitored for hypoglycemia.

When colesevelam is coadministered with glimepiride, maximum plasma concentration and total exposure to glimepiride is reduced. Therefore, Amaryl should be administered at least 4 hours prior to colesevelam.

## 4. DOSAGE FORMS AND STRENGTHS

AMARYL is formulated as tablets of:

- 1 mg (pink, oblong tablets, biplanar with score-line on both sides, imprinted on both sides).
- 2 mg (green, tablets, biplanar with score-line on both sides, imprinted on both sides).
- 3mg (yellow, tablets, biplanar with score-line on both sides, imprinted on both sides).
- 4 mg (blue, tablets, biplanar with score-line on both sides, imprinted on both sides).

Tablets for oral administration.

The tablets can be divided into two equal doses along the score line.

## 5. CONTRAINDICATIONS

AMARYL is contraindicated in patients with a history of a hypersensitivity reaction to:

- Glimepiride or any of the product's ingredients [see *Warnings and Precautions (5.2)*].
- Sulfonamide derivatives: Patients who have developed an allergic reaction to sulfonamide derivatives may develop an allergic reaction to AMARYL. Do not use AMARYL in patients who have a history of an allergic reaction to sulfonamide derivatives.

## 6. WARNINGS AND PRECAUTIONS

### 6.1 Hypoglycemia

All sulfonylureas, including AMARYL, can cause severe hypoglycemia [see *Adverse Reactions (6.1)*]. The patient's ability to concentrate and react may be impaired as a result of hypoglycemia. These impairments may present a risk in situations where these abilities are especially important, such as driving or operating other machinery. Severe hypoglycemia can lead to unconsciousness or convulsions and may result in temporary or permanent impairment of brain function or death.

Patients must be educated to recognize and manage hypoglycemia. Use caution when initiating and increasing AMARYL doses in patients who may be predisposed to hypoglycemia (e.g., the elderly, patients with renal impairment, patients on other anti-diabetic medications). Debilitated or malnourished patients, and those with adrenal, pituitary, or hepatic impairment are particularly susceptible to the hypoglycemic action of glucose-lowering medications. Hypoglycemia is also more likely to occur when caloric intake is deficient, after severe or prolonged exercise, or when alcohol is ingested.

Early warning symptoms of hypoglycemia may be different or less pronounced in patients with autonomic neuropathy, the elderly, and in patients who are taking beta-adrenergic blocking medications or other sympatholytic agents. These situations may result in severe hypoglycemia before the patient is aware of the hypoglycemia.

### 6.2 Hypersensitivity Reactions

There have been postmarketing reports of hypersensitivity reactions in patients treated with AMARYL, including serious reactions such as anaphylaxis, angioedema, and Stevens -Johnson Syndrome [see *Adverse Reactions (6.2)*]. If a hypersensitivity reaction is suspected, promptly

discontinue AMARYL, assess for other potential causes for the reaction, and institute alternative treatment for diabetes.

### **6.3 Hemolytic Anemia**

Sulfonylureas can cause hemolytic anemia in patients with glucose 6-phosphate dehydrogenase (G6PD) deficiency. Because AMARYL is a sulfonylurea, use caution in patients with G6PD deficiency and consider the use of a non-sulfonylurea alternative. There are also postmarketing reports of hemolytic anemia in patients receiving AMARYL who did not have known G6PD deficiency [see *Adverse Reactions (6.2)*].

### **6.4 Increased Risk of Cardiovascular Mortality with Sulfonylureas**

The administration of oral hypoglycemic drugs has been reported to be associated with increased cardiovascular mortality as compared to treatment with diet alone or diet plus insulin. This warning is based on the study conducted by the University Group Diabetes Program (UGDP), a long-term, prospective clinical trial designed to evaluate the effectiveness of glucose-lowering drugs in preventing or delaying vascular complications in patients with non-insulin-dependent diabetes. The study involved 823 patients who were randomly assigned to one of four treatment groups.

UGDP reported that patients treated for 5 to 8 years with diet plus a fixed dose of tolbutamide (1.5 grams per day) had a rate of cardiovascular mortality approximately 2 and a half times that of patients treated with diet alone. A significant increase in total mortality was not observed, but the use of tolbutamide was discontinued based on the increase in cardiovascular mortality, thus limiting the opportunity for the study to show an increase in overall mortality. Despite controversy regarding the interpretation of these results, the findings of the UGDP study provide an adequate basis for this warning. The patient should be informed of the potential risks and advantages of AMARYL and of alternative modes of therapy.

Although only one drug in the sulfonylurea class (tolbutamide) was included in this study, it is prudent from a safety standpoint to consider that this warning may also apply to other oral hypoglycemic drugs in this class, in view of their close similarities in mode of action and chemical structure.

### **6.5 Macrovascular Outcomes**

There have been no clinical studies establishing conclusive evidence of macrovascular risk reduction with AMARYL or any other anti-diabetic drug.

## **7. ADVERSE REACTIONS**

The following serious adverse reactions are discussed in more detail below and elsewhere in the labeling:

- Hypoglycemia [see *Warnings and Precautions (5.1)*]
- Hemolytic anemia [see *Warnings and Precautions (5.3)*]

## 7.1 Clinical Trials Experience

Because clinical trials are conducted under widely varying conditions, adverse reaction rates observed in the clinical trials of a drug cannot be directly compared to rates in the clinical trials of another drug and may not reflect the rates observed in practice.

Approximately 2,800 patients with type 2 diabetes have been treated with AMARYL in the controlled clinical trials. In these trials, approximately 1,700 patients were treated with AMARYL for at least 1 year. In clinical trials, the most common adverse reactions with AMARYL were hypoglycemia, dizziness, asthenia, headache, and nausea.

Table 1 summarizes adverse events, other than hypoglycemia, that were reported in 11 pooled placebo-controlled trials, whether or not considered to be possibly or probably related to study medication. Treatment duration ranged from 13 weeks to 12 months. Terms that are reported represent those that occurred at an incidence of  $\geq 5\%$  among AMARYL-treated patients and more commonly than in patients who received placebo.

**Table 1. Eleven Pooled Placebo-Controlled Trials ranging from 13 weeks to 12 months: Adverse Events (Excluding Hypoglycemia) Occurring in  $\geq 5\%$  of AMARYL-treated Patients and at a Greater Incidence than with Placebo\***

	<b>AMARYL N=745 %</b>	<b>Placebo N=294 %</b>
Headache	8.2	7.8
Accidental Injury <sup>†</sup>	5.8	3.4
Flu Syndrome	5.4	4.4
Nausea	5.0	3.4
Dizziness	5.0	2.4
*		

\*AMARYL doses ranged from 1-16 mg administered daily

<sup>†</sup>Insufficient information to determine whether any of the accidental injury events were associated with hypoglycemia

### Hypoglycemia:

In a randomized, double-blind, placebo-controlled monotherapy trial of 14 weeks duration, patients already on sulfonylurea therapy underwent a 3-week washout period then were randomized to AMARYL 1 mg, 4 mg, 8 mg or placebo. Patients randomized to AMARYL 4 mg or 8 mg underwent forced-titration from an initial dose of 1 mg to these final doses, as tolerated [see *Clinical Studies (14.1)*]. The overall incidence of possible hypoglycemia (defined by the presence of at least one symptom that the investigator believed might be related to hypoglycemia; a concurrent glucose measurement was not required) was 4% for AMARYL 1 mg, 17% for AMARYL 4 mg, 16% for AMARYL 8 mg and 0% for placebo. All of these events were self-treated.

In a randomized, double-blind, placebo-controlled monotherapy trial of 22 weeks duration, patients received a starting dose of either 1 mg AMARYL or placebo daily. The dose of AMARYL was titrated to a target fasting plasma glucose of 90-150 mg/dL. Final daily doses of

AMARYL were 1, 2, 3, 4, 6 or 8 mg [see *Clinical Studies (14.1)*]. The overall incidence of possible hypoglycemia (as defined above for the 14-week trial) for AMARYL vs. placebo was 19.7% vs. 3.2%. All of these events were self-treated.

#### Weight gain:

AMARYL, like all sulfonylureas, can cause weight gain [see *Clinical Studies (14.1)*].

#### Allergic Reactions:

In clinical trials, allergic reactions, such as pruritus, erythema, urticaria, and morbilliform or maculopapular eruptions, occurred in less than 1% of AMARYL-treated patients. These may resolve despite continued treatment with AMARYL. There are postmarketing reports of more serious allergic reactions (e.g., dyspnea, hypotension, shock) [see *Warnings and Precautions (5.2)*].

#### Laboratory Tests:

##### Elevated Serum Alanine Aminotransferase (ALT):

In 11 pooled placebo-controlled trials of AMARYL, 1.9% of AMARYL-treated patients and 0.8% of placebo-treated patients developed serum ALT greater than 2 times the upper limit of the reference range.

## **7.2 Postmarketing Experience**

The following adverse reactions have been identified during postapproval use of AMARYL. Because these reactions are reported voluntarily from a population of uncertain size, it is not always possible to reliably estimate their frequency or establish a causal relationship to drug exposure.

- Serious hypersensitivity reactions, including anaphylaxis, angioedema, and Stevens-Johnson Syndrome [see *Warnings and Precautions (5.2)*]
- Hemolytic anemia in patients with and without G6PD deficiency [see *Warnings and Precautions (5.3)*]
- Impairment of liver function (e.g. with cholestasis and jaundice), as well as hepatitis, which may progress to liver failure.
- Porphyria cutanea tarda, photosensitivity reactions and allergic vasculitis.
- Leukopenia, agranulocytosis, aplastic anemia, and pancytopenia.
- Thrombocytopenia: (including severe cases with platelet count less than 10,000/ $\mu$ l) and thrombocytopenic purpura.
- Hepatic porphyria reactions and disulfiram-like reactions
- Hyponatremia and syndrome of inappropriate antidiuretic hormone secretion (SIADH), most often in patients who are on other medications or who have medical conditions known to cause hyponatremia or increase release of antidiuretic hormone
- Dysgeusia
- Alopecia

## **8. DRUG INTERACTIONS**

### **8.1 Drugs Affecting Glucose Metabolism**

A number of medications affect glucose metabolism and may require AMARYL dose adjustment and particularly close monitoring for hypoglycemia or worsening glycemetic control.

The following are examples of medications that may increase the glucose-lowering effect of sulfonylureas including AMARYL, increasing the susceptibility to and/or intensity of hypoglycemia: oral anti-diabetic medications, pramlintide acetate, insulin, angiotensin converting enzyme (ACE) inhibitors, H<sub>2</sub> receptor antagonists, fibrates, propoxyphene, pentoxifylline, somatostatin analogs, anabolic steroids and androgens, cyclophosphamide, phenylramidol, guanethidine, fluconazole, sulfapyrazone, tetracyclines, clarithromycin, disopyramide, quinolones, and those drugs that are highly protein-bound, such as fluoxetine, nonsteroidal anti-inflammatory drugs, salicylates, sulfonamides, chloramphenicol, coumarins, probenecid and monoamine oxidase inhibitors. When these medications are administered to a patient receiving AMARYL, monitor the patient closely for hypoglycemia. When these medications are withdrawn from a patient receiving AMARYL, monitor the patient closely for worsening glycemetic control.

The following are examples of medications that may reduce the glucose-lowering effect of sulfonylureas including AMARYL, leading to worsening glycemetic control: danazol, glucagon, somatropin, protease inhibitors, atypical antipsychotic medications (e.g., olanzapine and clozapine), barbiturates, diazoxide, laxatives, rifampin, thiazides and other diuretics, corticosteroids, phenothiazines, thyroid hormones, estrogens, oral contraceptives, phenytoin, nicotinic acid, sympathomimetics (e.g., epinephrine, albuterol, terbutaline), and isoniazid. When these medications are administered to a patient receiving AMARYL, monitor the patient closely for worsening glycemetic control. When these medications are withdrawn from a patient receiving AMARYL, monitor the patient closely for hypoglycemia.

Beta-blockers, clonidine, and reserpine may lead to either potentiation or weakening of AMARYL's glucose-lowering effect.

Both acute and chronic alcohol intake may potentiate or weaken the glucose-lowering action of AMARYL in an unpredictable fashion.

The signs of hypoglycemia may be reduced or absent in patients taking sympatholytic drugs such as beta-blockers, clonidine, guanethidine, and reserpine.

### **8.2 Miconazole**

A potential interaction between oral miconazole and sulfonylureas leading to severe hypoglycemia has been reported. Whether this interaction also occurs with other dosage forms of miconazole is not known.

### **8.3 Cytochrome P450 2C9 Interactions**

There may be an interaction between glimepiride and inhibitors (e.g., fluconazole) and inducers (e.g., rifampin) of cytochrome P450 2C9. Fluconazole may inhibit the metabolism of

glimepiride, causing increased plasma concentrations of glimepiride which may lead to hypoglycemia. Rifampin may induce the metabolism of glimepiride, causing decreased plasma concentrations of glimepiride which may lead to worsening glycemic control.

#### **8.4 Concomitant Administration of Colesevelam**

Colesevelam can reduce the maximum plasma concentration and total exposure of glimepiride when the two are coadministered. However, absorption is not reduced when glimepiride is administered 4 hours prior to colesevelam. Therefore, Amaryl should be administered at least 4 hours prior to colesevelam.

### **9. USE IN SPECIFIC POPULATIONS**

#### **9.1 Pregnancy**

##### **Risk Summary**

Available data from a small number of published studies and postmarketing experience with AMARYL use in pregnancy over decades have not identified any drug associated risks for major birth defects, miscarriage, or adverse maternal outcomes. However, sulfonylureas (including glimepiride) cross the placenta and have been associated with neonatal adverse reactions such as hypoglycemia. Therefore, AMARYL should be discontinued at least two weeks before expected delivery (*see Clinical Considerations*). Poorly controlled diabetes in pregnancy is also associated with risks to the mother and fetus (*see Clinical Considerations*). In animal studies (*see Data*), there were no effects on embryo-fetal development following administration of glimepiride to pregnant rats and rabbits at oral doses approximately 4000 times and 60 times the maximum human dose based on body surface area, respectively. However, fetotoxicity was observed in rats and rabbits at doses 50 times and 0.1 times the maximum human dose, respectively.

The estimated background risk of major birth defects is 6% to 10% in women with pre-gestational diabetes with a HbA1c >7% and has been reported to be as high as 20% to 25% in women with a HbA1c >10%. The estimated background risk of miscarriage for the indicated population is unknown. In the U.S. general population, the estimated background risk of major birth defects and miscarriage in clinically recognized pregnancies is 2% to 4% and 15% to 20%, respectively.

##### **Clinical Considerations**

##### **Disease-associated maternal and/or embryo-fetal risk**

Poorly controlled diabetes in pregnancy increases the maternal risk for diabetic ketoacidosis, preeclampsia, spontaneous abortions, preterm delivery, and delivery complications. Poorly controlled diabetes increases the fetal risk for major birth defects, still birth, and macrosomia-related morbidity.

##### **Fetal/neonatal adverse reactions**

Neonates of women with gestational diabetes who are treated with sulfonylureas during pregnancy may be at increased risk for neonatal intensive care admission and may develop respiratory distress, hypoglycemia, birth injury, and be large for gestational age. Prolonged severe hypoglycemia, lasting 4–10 days, has been reported in neonates born to mothers receiving a

sulfonylurea at the time of delivery and has been reported with the use of agents with a prolonged half-life. Observe newborns for symptoms of hypoglycemia and respiratory distress and manage accordingly.

### **Dose adjustments during pregnancy and the postpartum period**

Due to reports of prolonged severe hypoglycemia in neonates born to mothers receiving a sulfonylurea at the time of delivery, AMARYL should be discontinued at least two weeks before expected delivery (*see Fetal/Neonatal Adverse Reactions*).

### **Data**

#### **Animal data**

In animal studies, there was no increase in congenital anomalies, but an increase in fetal deaths occurred in rats and rabbits at glimepiride doses 50 times (rats) and 0.1 times (rabbits) the maximum recommended human dose (based on body surface area). This fetotoxicity was observed only at doses inducing maternal hypoglycemia and is believed to be directly related to the pharmacologic (hypoglycemic) action of glimepiride, as has been similarly noted with other sulfonylureas.

## **9.2 Lactation**

### **Risk Summary**

Breastfed infants of lactating women using AMARYL should be monitored for symptoms of hypoglycemia (*see Clinical Considerations*). It is not known whether glimepiride is excreted in human milk and there are no data on the effects of glimepiride on milk production. Glimepiride is present in rat milk [*see Data*]. The developmental and health benefits of breastfeeding should be considered along with the mother's clinical need for AMARYL and any potential adverse effects on the breastfed child from AMARYL or from the underlying maternal condition.

### **Clinical Considerations**

#### **Monitoring for adverse reactions**

Monitor breastfed infants for signs of hypoglycemia (e.g., jitters, cyanosis, apnea, hypothermia, excessive sleepiness, poor feeding, seizures).

### **Data**

During prenatal and postnatal studies in rats, significant concentrations of glimepiride were present in breast milk and the serum of the pups. Offspring of rats exposed to high levels of glimepiride during pregnancy and lactation developed skeletal deformities consisting of shortening, thickening, and bending of the humerus during the postnatal period. These skeletal deformations were determined to be the result of nursing from mothers exposed to glimepiride.

### 9.3 Pediatric Use

The pharmacokinetics, efficacy and safety of AMARYL have been evaluated in pediatric patients with type 2 diabetes as described below. AMARYL is not recommended in pediatric patients because of its adverse effects on body weight and hypoglycemia.

The pharmacokinetics of a 1 mg single dose of AMARYL was evaluated in 30 patients with type 2 diabetes (male = 7; female = 23) between ages 10 and 17 years. The mean ( $\pm$  SD)  $AUC_{(0-last)}$  ( $339\pm 203$  ng•hr/mL),  $C_{max}$  ( $102\pm 48$  ng/mL) and  $t_{1/2}$  ( $3.1\pm 1.7$  hours) for glimepiride were comparable to historical data from adults ( $AUC_{(0-last)}$   $315\pm 96$  ng•hr/mL,  $C_{max}$   $103\pm 34$  ng/mL and  $t_{1/2}$   $5.3\pm 4.1$  hours).

The safety and efficacy of AMARYL in pediatric patients was evaluated in a single-blind, 24-week trial that randomized 272 patients (8-17 years of age) with type 2 diabetes to AMARYL (n=135) or metformin (n=137). Both treatment-naive patients (those treated with only diet and exercise for at least 2 weeks prior to randomization) and previously treated patients (those previously treated or currently treated with other oral antidiabetic medications for at least 3 months) were eligible to participate. Patients who were receiving oral antidiabetic agents at the time of study entry discontinued these medications before randomization without a washout period. AMARYL was initiated at 1 mg, and then titrated up to 2, 4 or 8 mg (mean last dose 4 mg) through Week 12, targeting a self-monitored fasting finger-stick blood glucose < 126 mg/dL. Metformin was initiated at 500 mg twice daily and titrated at Week 12 up to 1000 mg twice daily (mean last dose 1365 mg).

After 24 weeks, the overall mean treatment difference in HbA1c between AMARYL and metformin was 0.2%, favoring metformin (95% confidence interval -0.3% to +0.6%). Based on these results, the trial did not meet its primary objective of showing a similar reduction in HbA1c with AMARYL compared to metformin.

**Table 2: Change from Baseline in HbA1c and Body Weight in Pediatric Patients Taking Amaryl or Metformin**

	<b>Metformin</b>	<b>AMARYL</b>
<b>Treatment- Naive Patients*</b>	N=69	N=72
<b>HbA1c (%)</b>		
Baseline (mean)	8.2	8.3
Change from baseline (adjusted LS mean) +	-1.2	-1.0
Adjusted Treatment Difference** (95%CI)	0.2 (-0.3; 0.6)	
<b>Previously Treated Patients*</b>	N=57	N=55
<b>HbA1c (%)</b>		
Baseline (mean)	9.0	8.7
Change from baseline (adjusted LS mean) +	-0.2	0.2
Adjusted Treatment Difference † (95%CI)	0.4 (-0.4; 1.2)	
<b>Body Weight (kg)*</b>	N=126	N=129
Baseline (mean)	67.3	66.5
Change from baseline (adjusted LS mean)+	0.7	2.0

Adjusted Treatment Difference <sup>‡</sup> (95% CI)	1.3 (0.3; 2.3)
--	----------------

\* Intent-to-treat population using last-observation-carried-forward for missing data (AMARYL, n=127; metformin, n=126)

+ adjusted for baseline HbA1c and Tanner Stage

<sup>‡</sup> Difference is AMARYL – metformin with positive differences favoring metformin

The profile of adverse reactions in pediatric patients treated with AMARYL was similar to that observed in adults [see *Adverse Reactions (6)*].

Hypoglycemic events documented by blood glucose values <36 mg/dL were observed in 4% of pediatric patients treated with AMARYL and in 1% of pediatric patients treated with metformin. One patient in each treatment group experienced a severe hypoglycemic episode (severity was determined by the investigator based on observed signs and symptoms).

#### 9.4 Geriatric Use

In clinical trials of AMARYL, 1053 of 3491 patients (30%) were >65 years of age. No overall differences in safety or effectiveness were observed between these patients and younger patients, but greater sensitivity of some older individuals cannot be ruled out.

There were no significant differences in glimepiride pharmacokinetics between patients with type 2 diabetes ≤65 years (n=49) and those >65 years (n=42) [see *Clinical Pharmacology (12.3)*].

Glimepiride is substantially excreted by the kidney. Elderly patients are more likely to have renal impairment. In addition, hypoglycemia may be difficult to recognize in the elderly [see *Dosage and Administration (2.1)* and *Warnings and Precautions (5.1)*]. Use caution when initiating AMARYL and increasing the dose of AMARYL in this patient population.

#### 9.5 Renal Impairment

To minimize the risk of hypoglycemia, the recommended starting dose of AMARYL is 1 mg daily for all patients with type 2 diabetes and renal impairment [see *Dosage and Administration (2.1)* and *Warnings and Precautions (5.1)*].

A multiple-dose titration study was conducted in 16 patients with type 2 diabetes and renal impairment using doses ranging from 1 mg to 8 mg daily for 3 months. Baseline creatinine clearance ranged from 10-60 mL/min. The pharmacokinetics of AMARYL was evaluated in the multiple-dose titration study and the results were consistent with those observed in patients enrolled in a single-dose study. In both studies, the relative total clearance of AMARYL increased when kidney function was impaired. Both studies also demonstrated that the elimination of the two major metabolites was reduced in patients with renal impairment [see *Clinical Pharmacology (12.3)*].

## 10. OVERDOSAGE

An overdose of AMARYL, as with other sulfonylureas, can produce severe hypoglycemia. Mild episodes of hypoglycemia can be treated with oral glucose. Severe hypoglycemic reactions constitute medical emergencies requiring immediate treatment. Severe hypoglycemia with coma, seizure, or neurological impairment can be treated with glucagon or intravenous glucose. Continued observation and additional carbohydrate intake may be necessary because hypoglycemia may recur after apparent clinical recovery [see *Warnings and Precautions (5.1)*].

## 11. DESCRIPTION

AMARYL is an oral sulfonylurea that contains the active ingredient glimepiride. Chemically, glimepiride is identified as 1-[[p-[2-(3-ethyl-4-methyl-2-oxo-3-pyrroline-1-carboxamido)ethyl]phenyl]sulfonyl]-3-(trans-4-methylcyclohexyl)urea (C<sub>24</sub>H<sub>34</sub>N<sub>4</sub>O<sub>5</sub>S) with a molecular weight of 490.62. Glimepiride is a white to yellowish-white, crystalline, odorless to practically odorless powder and is practically insoluble in water.

The structural formula is:

AMARYL tablets contain the active ingredient glimepiride and the following inactive ingredients:

Lactose monohydrate, microcrystalline cellulose, sodium starch glycolate, plividone 25000, magnesium stearate.

In addition, AMARYL 1 mg tablets contain Red Ferric Oxide (E172), AMARYL 2 mg tablets contain Yellow Ferric Oxide and Indigo Carmine Aluminum Lake (E312), AMARYL 3mg tablets contain Yellow Ferric Oxide (E172) and AMARYL 4 mg tablets contain Indigo Carmine Aluminum Lake (E312).

## 12. CLINICAL PHARMACOLOGY

### 12.1 Mechanism of Action

Glimepiride primarily lowers blood glucose by stimulating the release of insulin from pancreatic beta cells. Sulfonylureas bind to the sulfonylurea receptor in the pancreatic beta-cell plasma membrane, leading to closure of the ATP-sensitive potassium channel, thereby stimulating the release of insulin.

### 12.2 Pharmacodynamics

In healthy subjects, the time to reach maximal effect (minimum blood glucose concentrations) was approximately 2-3 hours after single oral doses of AMARYL. The effects of AMARYL on HbA<sub>1c</sub>, fasting plasma glucose, and post-prandial glucose have been assessed in clinical trials [see *Clinical Studies (14)*].

## 12.3 Pharmacokinetics

### Absorption:

Studies with single oral doses of glimepiride in healthy subjects and with multiple oral doses in patients with type 2 diabetes showed peak drug concentrations ( $C_{max}$ ) 2 to 3 hours post-dose. When glimepiride was given with meals, the mean  $C_{max}$  and AUC (area under the curve) were decreased by 8% and 9%, respectively.

Glimepiride does not accumulate in serum following multiple dosing. The pharmacokinetics of glimepiride does not differ between healthy subjects and patients with type 2 diabetes. Clearance of glimepiride after oral administration does not change over the 1 mg to 8 mg dose range, indicating linear pharmacokinetics.

In healthy subjects, the intra- and inter-individual variabilities of glimepiride pharmacokinetic parameters were 15-23% and 24-29%, respectively.

### Distribution:

After intravenous dosing in healthy subjects, the volume of distribution ( $V_d$ ) was 8.8 L (113 mL/kg), and the total body clearance (CL) was 47.8 mL/min. Protein binding was greater than 99.5%.

### Metabolism:

Glimepiride is completely metabolized by oxidative biotransformation after either an intravenous or oral dose. The major metabolites are the cyclohexyl hydroxy methyl derivative (M1) and the carboxyl derivative (M2). Cytochrome P450 2C9 is involved in the biotransformation of glimepiride to M1. M1 is further metabolized to M2 by one or several cytosolic enzymes. M2 is inactive. In animals, M1 possesses about one-third of the pharmacological activity of glimepiride, but it is unclear whether M1 results in clinically meaningful effects on blood glucose in humans.

### Excretion:

When  $^{14}C$ -glimepiride was given orally to 3 healthy male subjects, approximately 60% of the total radioactivity was recovered in the urine in 7 days. M1 and M2 accounted for 80-90% of the radioactivity recovered in the urine. The ratio of M1 to M2 in the urine was approximately 3:2 in two subjects and 4:1 in one subject. Approximately 40% of the total radioactivity was recovered in feces. M1 and M2 accounted for about 70% (ratio of M1 to M2 was 1:3) of the radioactivity recovered in feces. No parent drug was recovered from urine or feces. After intravenous dosing in patients, no significant biliary excretion of glimepiride or its M1 metabolite was observed.

## **Specific Populations**

### **Geriatric Patients:**

A comparison of glimepiride pharmacokinetics in patients with type 2 diabetes  $\leq 65$  years and those  $>65$  years was evaluated in a multiple-dose study using AMARYL 6 mg daily. There were no significant differences in glimepiride pharmacokinetics between the two age groups. The mean AUC at steady state for the older patients was approximately 13% lower than that for the younger patients; the mean weight-adjusted clearance for the older patients was approximately 11% higher than that for the younger patients.

### **Gender:**

There were no differences between males and females in the pharmacokinetics of glimepiride when adjustment was made for differences in body weight.

### **Race:**

No studies have been conducted to assess the effects of race on glimepiride pharmacokinetics but in placebo-controlled trials of AMARYL in patients with type 2 diabetes, the reduction in HbA1c was comparable in Caucasians (n = 536), blacks (n = 63), and Hispanics (n = 63).

### **Renal Impairment:**

In a single-dose, open-label study AMARYL 3 mg was administered to patients with mild, moderate and severe renal impairment as estimated by creatinine clearance (CL<sub>cr</sub>): Group I consisted of 5 patients with mild renal impairment (CL<sub>cr</sub> > 50 mL/min), Group II consisted of 3 patients with moderate renal impairment (CL<sub>cr</sub> = 20-50 mL/min) and Group III consisted of 7 patients with severe renal impairment (CL<sub>cr</sub> < 20 mL/min). Although, glimepiride serum concentrations decreased with decreasing renal function, Group III had a 2.3-fold higher mean AUC for M1 and an 8.6-fold higher mean AUC for M2 compared to corresponding mean AUCs in Group I. The apparent terminal half-life ( $T_{1/2}$ ) for glimepiride did not change, while the half-lives for M1 and M2 increased as renal function decreased. Mean urinary excretion of M1 plus M2 as a percentage of dose decreased from 44.4% for Group I to 21.9% for Group II and 9.3% for Group III.

### **Hepatic Impairment:**

It is unknown whether there is an effect of hepatic impairment on AMARYL pharmacokinetics because the pharmacokinetics of AMARYL has not been adequately evaluated in patients with hepatic impairment.

### **Obese Patients:**

The pharmacokinetics of glimepiride and its metabolites were measured in a single-dose study involving 28 patients with type 2 diabetes who either had normal body weight or were morbidly obese. While the  $t_{max}$ , clearance, and volume of distribution of glimepiride in the morbidly obese patients were similar to those in the normal weight group, the morbidly obese had lower  $C_{max}$  and

AUC than those of normal body weight. The mean  $C_{\max}$ ,  $AUC_{0-24}$ ,  $AUC_{0-\infty}$  values of glimepiride in normal vs. morbidly obese patients were  $547 \pm 218$  ng/mL vs.  $410 \pm 124$  ng/mL,  $3210 \pm 1030$  hours·ng/mL vs.  $2820 \pm 1110$  hours·ng/mL and  $4000 \pm 1320$  hours·ng/mL vs.  $3280 \pm 1360$  hours·ng/mL, respectively.

#### Drug Interactions:

##### Aspirin:

In a randomized, double-blind, two-period, crossover study, healthy subjects were given either placebo or aspirin 1 gram three times daily for a total treatment period of 5 days. On Day 4 of each study period, a single 1 mg dose of AMARYL was administered. The AMARYL doses were separated by a 14-day washout period. Co-administration of aspirin and AMARYL resulted in a 34% decrease in the mean glimepiride AUC and a 4% decrease in the mean glimepiride  $C_{\max}$ .

##### Colesevelam:

Concomitant administration of colesevelam and glimepiride resulted in reductions in glimepiride  $AUC^{0-\infty}$  and  $C_{\max}$  of 18% and 8%, respectively. When glimepiride was administered 4 hours prior to colesevelam, there was no significant change in glimepiride  $AUC^{0-\infty}$  or  $C_{\max}$ , -6% and 3%, respectively [see *Dosage and Administration (2.1)* and *Drug Interactions (7.4)*].

##### Cimetidine and Ranitidine:

In a randomized, open-label, 3-way crossover study, healthy subjects received either a single 4 mg dose of AMARYL alone, AMARYL with ranitidine (150 mg twice daily for 4 days; AMARYL was administered on Day 3), or AMARYL with cimetidine (800 mg daily for 4 days; AMARYL was administered on Day 3). Co-administration of cimetidine or ranitidine with a single 4 mg oral dose of AMARYL did not significantly alter the absorption and disposition of glimepiride.

##### Propranolol:

In a randomized, double-blind, two-period, crossover study, healthy subjects were given either placebo or propranolol 40 mg three times daily for a total treatment period of 5 days. On Day 4 or each study period, a single 2 mg dose of AMARYL was administered. The AMARYL doses were separated by a 14-day washout period. Concomitant administration of propranolol and AMARYL significantly increased glimepiride  $C_{\max}$ , AUC, and  $T_{1/2}$  by 23%, 22%, and 15%, respectively, and decreased glimepiride CL/f by 18%. The recovery of M1 and M2 from urine was not changed.

##### Warfarin:

In an open-label, two-way, crossover study, healthy subjects received 4 mg of AMARYL daily for 10 days. Single 25 mg doses of warfarin were administered 6 days before starting AMARYL and on Day 4 of AMARYL administration. The concomitant administration of AMARYL did not alter the pharmacokinetics of R- and S-warfarin enantiomers. No changes were observed in warfarin plasma protein binding. AMARYL resulted in a statistically significant decrease in the pharmacodynamic response to warfarin. The reductions in mean area under the prothrombin time

(PT) curve and maximum PT values during AMARYL treatment were 3.3% and 9.9%, respectively, and are unlikely to be clinically relevant.

## 13. NONCLINICAL TOXICOLOGY

### 13.1 Carcinogenesis, Mutagenesis, and Impairment of Fertility

Studies in rats at doses of up to 5000 parts per million (ppm) in complete feed (approximately 340 times the maximum recommended human dose, based on surface area) for 30 months showed no evidence of carcinogenesis. In mice, administration of glimepiride for 24 months resulted in an increase in benign pancreatic adenoma formation that was dose-related and was thought to be the result of chronic pancreatic stimulation. No adenoma formation in mice was observed at a dose of 320 ppm in complete feed, or 46-54 mg/kg body weight/day. This is about 35 at least 28 times the maximum human recommended dose of 8 mg once daily based on surface area.

Glimepiride was non-mutagenic in a battery of *in vitro* and *in vivo* mutagenicity studies (Ames test, somatic cell mutation, chromosomal aberration, unscheduled DNA synthesis, and mouse micronucleus test).

There was no effect of glimepiride on male mouse fertility in animals exposed up to 2500 mg/kg body weight (>1, 500 times the maximum recommended human dose based on surface area). Glimepiride had no effect on the fertility of male and female rats administered up to 4000 mg/kg body weight (approximately 4,000 times the maximum recommended human dose based on surface area).

## 14. CLINICAL STUDIES

### 14.1 Monotherapy

A total of 304 patients with type 2 diabetes already treated with sulfonylurea therapy participated in a 14-week, multicenter, randomized, double-blind, placebo-controlled trial evaluating the safety and efficacy of AMARYL monotherapy. Patients discontinued their sulfonylurea therapy then entered a 3-week placebo washout period followed by randomization into 1 of 4 treatment groups: placebo (n=74), AMARYL 1 mg (n=78), AMARYL 4 mg (n=76) and AMARYL 8 mg (n=76). All patients randomized to AMARYL started 1 mg daily. Patients randomized to AMARYL 4 mg or 8 mg had blinded, forced titration of the AMARYL dose at weekly intervals, first to 4 mg and then to 8 mg, as long as the dose was tolerated, until the randomized dose was reached. Patients randomized to the 4 mg dose reached the assigned dose at Week 2. Patients randomized to the 8 mg dose reached the assigned dose at Week 3. Once the randomized dose level was reached, patients were to be maintained at that dose until Week 14. Approximately 66% of the placebo-treated patients completed the trial compared to 81% of patients treated with glimepiride 1 mg and 92% of patients treated with glimepiride 4 mg or 8 mg. Compared to placebo, treatment with AMARYL 1 mg, 4 mg and 8 mg daily provided statistically significant improvements in HbA1C compared to placebo (Table 3).

**Table 3. 14-week Monotherapy Trial Comparing AMARYL to Placebo in Patients Previously Treated With Sulfonylurea Therapy<sup>a</sup>**

	Placebo (N=74)	AMARYL		
		1 mg (N=78)	4 mg (N=76)	8 mg (N=76)
<b>HbA1c (%)</b>				
	n=59	n=65	n=65	n=68
Baseline (mean)	8.0	7.9	7.9	8.0
Change from Baseline (adjusted mean <sup>b</sup> )	1.5	0.3	-0.3	-0.4
Difference from Placebo (adjusted mean <sup>b</sup> ) 95% confidence interval		-1.2* (-1.5, -0.8)	-1.8* (-2.1, -1.4)	-1.8* (-2.2, -1.5)
<b>Mean Baseline Weight (kg)</b>				
	n=67	n=76	n=75	n=73

\*p<0.001

A total of 249 patients who were treatment- naive or who had received limited treatment with antidiabetic therapy in the past were randomized to receive 22 weeks of treatment with either AMARYL (n=123) or placebo (n=126) in a multicenter, randomized, double-blind, placebo-controlled, dose-titration trial. The starting dose of AMARYL was 1 mg daily and was titrated upward or downward at 2-week intervals to a goal FPG of 90-150 mg/dL. Blood glucose levels for both FPG and PPG were analyzed in the laboratory. Following 10 weeks of dose adjustment, patients were maintained at their optimal dose (1, 2, 3, 4, 6 or 8 mg) for the remaining 12 weeks of the trial. Treatment with AMARYL provided statistically significant improvements in HbA1c and FPG compared to placebo (Table 4).

**Table 4: 22-Week Monotherapy Trial Comparing AMARYL to Placebo in Patients Who Were Treatment-Naïve or Who Had No Recent Treatment with Antidiabetic Therapy<sup>a</sup>**

	<b>Placebo (N=126)</b>	<b>AMARYL (N=123)</b>
<b>HbA1c (%)</b>	n=97	n=106
Baseline (mean)	9.1	9.3
Change from Baseline (adjusted mean <sup>b</sup> )	-1.1*	-2.2*

## 15. HOW SUPPLIED/STORAGE AND HANDLING

AMARYL tablets are available in the following strengths and package sizes:  
1mg, 2mg, 3mg, 4mg.

### Presentation

Each pack contains 30 tablets.

### Storage

Do not store above 30°C.

## MANUFACTURER

Sanofi S.p.A., Italy.

## LICENSE HOLDER

Sanofi Aventis Israel Ltd., P.O.B 8090, Netanya 4250499.
